Preauthorization is not required.

The following protocol contains medical necessity criteria that apply for this service. The criteria are also applicable to services provided in the local Medicare Advantage operating area for those members, unless separate Medicare Advantage criteria are indicated. If the criteria are not met, reimbursement will be denied and the patient cannot be billed. Please note that payment for covered services is subject to eligibility and the limitations noted in the patient’s contract at the time the services are rendered.

Description

Electromagnetic navigation bronchoscopy (ENB) is intended to enhance standard bronchoscopy by providing a three-dimensional roadmap of the lungs and real-time information about the position of the steerable probe during bronchoscopy. The purpose of ENB is to allow navigation to distal regions of the lungs, so that suspicious lesions can be biopsied to allow fiducial markers placement.

Policy

Electromagnetic navigation bronchoscopy (ENB) is considered medically necessary in patients with solitary pulmonary nodules in which:

• malignancy is reasonably suspected and
• it has been determined that a tissue diagnosis is required and
• percutaneous lung biopsy is considered high risk and low probability for diagnostic yield and
• standard bronchoscopy and/or endobronchial ultrasound (EBUS) are considered low probability for diagnostic yield.

ENB is considered medically necessary in patients with an identified lung lesion(s) and a coexisting cancer in whom:
• further determination of the lung lesion may impact the staging of the primary malignancy, and the treatment and
• percutaneous lung biopsy is considered high risk and low probability for diagnostic yield and
• standard bronchoscopy and/or EBUS are considered low probability for diagnostic yield.

Electromagnetic navigation bronchoscopy is considered medically necessary for the placement of fiducial markers in patients who are to undergo radiotherapeutic treatment of malignant solitary pulmonary nodules when:
• they are not surgical candidates and radiation treatment is the preferred treatment and
• it is determined that the location of the nodules makes placement of fiducial markers by a transthoracic approach likely to be associated with high risk of developing significant pneumothorax.

Electromagnetic navigation bronchoscopy is considered medically necessary for the placement of fiducial markers to help localize a nodule by fluoroscopy during thorascopic excision that would otherwise not be palpable without a thoracotomy.

All other uses of ENB are considered investigational.

Background
Pulmonary nodules are identified on plain chest radiographs or chest computed tomography (CT) scans. Although most nodules are benign, some are cancerous, and early diagnosis of lung cancer is desirable because of the poor prognosis when it is diagnosed later. The method used to diagnose lung cancer depends on a number of factors, including lesion size and location, as well as the clinical history and status of the patient.

Peripheral lung lesions and solitary pulmonary nodules (most often defined as asymptomatic nodules less than six mm) are more difficult to evaluate than larger, centrally located lesions. There are several options for diagnosing them; none of the methods is ideal for safely and accurately diagnosing malignant disease. Sputum cytology is the least invasive approach. Reported sensitivity rates are relatively low and vary widely across studies; sensitivity is lower for peripheral lesions. Sputum cytology, however, has a high specificity; and a positive test may obviate the need for more invasive testing. Flexible bronchoscopy, a minimally invasive procedure, is an established approach to evaluate pulmonary nodules. The sensitivity of flexible bronchoscopy for diagnosing bronchogenic carcinoma has been estimated at 88% for central lesions and 78% for peripheral lesions. For small peripheral lesions (less than 1.5 cm in diameter), the sensitivity may be as low as 10%. The diagnostic accuracy of transthoracic needle aspiration for solitary pulmonary nodules tends to be higher than that of bronchoscopy; the sensitivity and specificity are both approximately 94%. A disadvantage of transthoracic needle aspiration is that a pneumothorax develops in 11% to 24% of patients, and 5% to 14% require insertion of a chest tube. Positron emission tomography scans are also highly sensitive for evaluating pulmonary nodules, yet may miss lesions less than one cm in size. Lung biopsy is the criterion standard for diagnosing pulmonary nodules but is an invasive procedure.\(^1\), \(^2\)
Recent advances in technology may increase the yield of established diagnostic methods. CT scanning equipment can be used to guide bronchoscopy and bronchoscopic transbronchial needle biopsy but have the disadvantage of exposing the patient and staff to radiation. Endobronchial ultrasound (EBUS) by radial probes, previously used in the perioperative staging of lung cancer, can also be used to locate and guide sampling of peripheral lesions. EBUS is reported to increase the diagnostic yield of flexible bronchoscopy to at least 82%, regardless of lesion size or location.\textsuperscript{1}

Another proposed enhancement to standard bronchoscopy is electromagnetic navigation bronchoscopy (ENB). ENB is intended to enhance standard bronchoscopy by providing a three-dimensional roadmap of the lungs and real-time information about the position of the steerable probe during bronchoscopy. The purpose of ENB is to allow navigation to distal regions of the lungs. Once the navigation catheter is in place, any endoscopic tool can be inserted through the channel in the catheter to the target. This includes insertion of transbronchial forceps to biopsy the lesion. In addition, the guide catheter can be used to place fiducial markers. Markers are loaded in the proximal end of the catheter with a guide wire inserted through the catheter.

**Regulatory Status**

In September 2004, the SuperDimension/Bronchus™ InReach™ system (superDimension, Herzliya, Israel) was cleared for marketing by the U.S. Food and Drug Administration (FDA) through the 510(k) process. The system includes planning and navigation software, a disposable extended working channel, and a disposable steerable guide. The FDA-cleared indication is for displaying images of the tracheobronchial tree that aids physicians in guiding endoscopic tools in the pulmonary tract. The device is not intended as an endoscopic tool; it does not make a diagnosis; and it is not approved for pediatric use. As of June 2016, the current version of the product is the Medtronic SuperDimension Navigation System (Medtronic, Minneapolis, MN).

In December 2009, the ig4™ EndoBronchial system (Veran Medical, St. Louis, MO) was cleared for marketing by FDA through the 510(k) process. The system was considered to be substantially equivalent to the InReach system and is marketed as the SPiN™ Drive system.

Several additional navigation software-only systems have been cleared for marketing by FDA through the 510(k) process. They include:

- In December 2008, the LungPoint® virtual bronchoscopic navigation (VPN) system (Broncus Technologies, Mountain View, CA).
- In June 2010, the bf-NAVI VPN system (Emergo Group, Austin, TX).

FDA product codes: JAK and LLZ.
